

Common Intradermal Injection Sites

When it comes to intradermal injection sites, you've got a few reliable options.

Nurses choose this area for their accessibility and thin dermal layers:

- **Inner forearm (inner aspect):** The most used site for TB tests and often used for allergy testing.
- **Upper back:** A preferred site for allergy tests, the testing area may involve the entire back depending on the number of allergens tested and the size of the client's back.
